### Question 4 Red & Yellow Flowers

[20 marks] You are given an array of  $n$  flowers that are either red or yellow. Your goal is to find the number of subarrays where there are more red flowers contained within the subarray, than there are yellow flowers outside the subarray.

**4.1 [6 marks]** Describe a method that runs in  $O(n)$  time, which pre-processes the input array such that you can then calculate the number of red flowers within any contiguous subarray in  $O(1)$  time.

We create an array  $R$  to store the numbers of red flowers, and the index  $i$  presents the current index which we count it to. ( $R[0]$  means the number of red flowers from index 0 to index 0,  $R[i]$  means the numbers of red flowers that we accumulate from index 0 to index  $i$ ).

Check if the first element is red or yellow:

Case 1: If the first element is yellow flower, then  $R[0] = 0$ .

Case 2: If the first element is red flower, then  $R[0] = 1$ .

Calculating the  $R[i]$  (the numbers of red flowers that we accumulate from index 0 to index  $i$ .)

If the  $i$ -th flower is yellow,  $R[i] = R[i-1] + 0$ .

Otherwise if the  $i$ -th flower is red,  $R[i] = R[i-1] + 1$ .

There is base case when  $i = 0$ , we return  $R[i]$  since we can't count  $R[0-1]$ . (The case is counting the number of red flowers from index 0 to index 0)

#### *Time complexity*

The time complexity we get accessed into the element in the array takes  $O(1)$ . And since we create the array which traverses  $R$  from 0 to  $n-1$ , the time complexity is  $O(n)$ . As the result, the final time complexity is  $O(n)$ .

**4.2 [14 marks]** Design an algorithm that achieves your goal in  $O(n \log n)$  time.

Let the cumulative number of red and yellow flowers be  $R[n]$  and  $Y[n]$  respectively.

Our goal is to find the number of index pairs  $\{i, j\}$  ( $0 \leq i < j < n$ ) such that  $R[j] - R[i] > Y[j] - Y[i]$ .

The inequality above can be transformed into  $Y[j] - R[j] < Y[i] - R[i]$ .

We can create a new array  $\text{Diff}[1 \dots n] = Y[1 \dots n] - R[1 \dots n]$ , therefore the original goal can be rewritten to: Find the number of pairs  $\{i, j\}$  ( $0 \leq i < j < n$ ) such that  $\text{Diff}[j] < \text{Diff}[i]$ . That is, to find the number of inversion pairs of the array  $\text{Diff}$ , which can be solved by merge sort in  $O(n \log n)$ .

Let  $\text{count}$  be the number of subarrays which contain more red flowers than yellow flowers.

For base case, if  $\text{Diff}[i] < 0$  then increase  $\text{count}$  by 1.

### *Complexity*

Since we apply the merge sort, the time complexity is  $O(n \log n)$ .
